Flappy bird 玩法

https://www.youtube.com/watch?v=I69adfEqwC0

Motivation

Flappy Bird是一款使用pygame所開發出的遊戲, 但是是用鍵盤來遊玩。而我們想要用STM32 board來達成用手部來操作遊戲的功能, 讓玩家有更真實的遊戲體驗。

我們使用 STM32 board內建的三軸加速度感測器來偵測玩家的手部動作,來控制遊戲內的鳥來移動。

Concepts used in class

STM32

Eventqueue

MultiThread

Wifi(TCP connection)

DigitalIn

3-axis accelerate sensor

How to play

遊戲操作方式有五種。

- 1.按住User Button同時向上傾斜(根據傾斜程度不同而有不同的上升幅度): 可以觸發Flappy Bird往上飛
- 2.按住User Button同時向下傾斜(根據傾斜程度不同而有不同的下降幅度): 可以觸發Flappy Bird往下掉
- 3.不按User Button或按住User Button傾斜程度不大時:可以固定Flappy Bird的高度

能以低延遲、高精確度的操控來玩遊戲

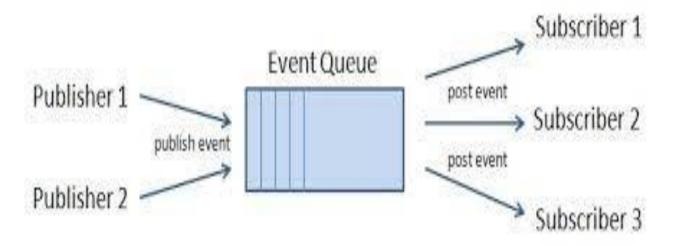

Flow chart

TCP connection Server Client **Get Data Data Preprocessing** Send Data **Determine Action Update Character**

Eventqueue(Every 5ms)

Eventqueue

Use eventqueue to schedule events

Data Preprocessing

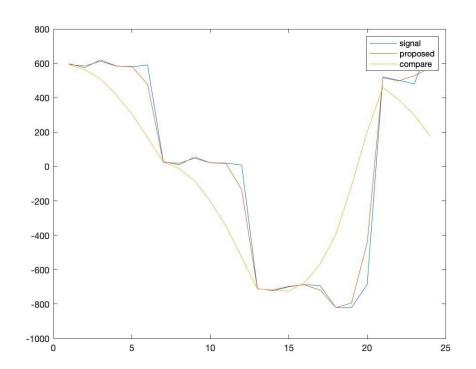

- To enhance the user's quality of experience (QoE), we need to do data pre-processing to determine the action more accurately.
- 我們參考 smoothed round trip time SRTT = (ALPHA * SRTT) + ((1-ALPHA) * RTT) formula in TCP.
- Eventually, we adopt another threshold 0.2 * previous data
 + 0.8 * present data, which can achieve better QoE.

Smooth filter

Tradeoff between smooth signal and edge

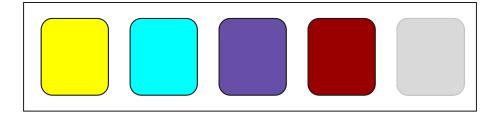

Bilateral Filter!?
Complex calculation!!

Compare h=[0.05, 0.1, 0.15, 0.2, 0.25, 0.25] Proposed h=[0.2, 0.8]

Data Preprocessing

Method:using queue(STL library) to calculate weighted average

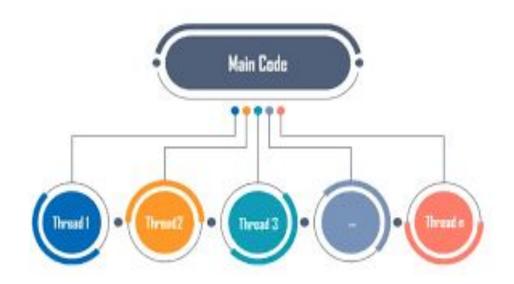

Action

-980<data[y]<980

Server

Server端採用multithreaded的方式,一個thread處理遊戲畫面,另一個thread 負責接收stm32 board所傳來的資料(已在client端處理完)
